PART III: HAZARD ASSESSMENT

GROUNDWATER ROUTE

1. Describe the likelihood of a release of contaminant(s) to the groundwater as follows: observed, alleged, potential, or none. Identify the contaminant(s) detected or suspected, and provide a rationale for attributing the contaminant(s) to the facility.

During the years that the leaching lagoon was operational, there was a strong potential that a release of metal-contaminated water to groundwater occurred. The leaching lagoon is no longer used, and the hazardous substances are stored in a bermed area of the building until they are removed by a licensed waste hauler.

Ref. Nos. 10, 11, 12, 13, 14, 15, 16, 17

2. Describe the aquifer of concern; include information such as depth, thickness, geologic composition, permeability, overlying strata, confining layers, interconnections, discontinuities, depth to water table, groundwater flow direction.

Directly beneath the site, the Magothy aquifer is the aquifer of concern, and its surface lies at an elevation of approximately -150 ft mean sea level (MSL). The Magothy aquifer exists in the Matawan Group Magothy Formation. This clay, silt, sandy clay, and fine to medium sand formation is approximately 600 ft thick. A large quantity of clay in the upper portion of the Magothy causes water to become confined and may even cause the formation to display artesian conditions with depth. The Magothy displays moderate to high permeability. The Magothy also displays a high degree of hydraulic continuity with the overlying upper glacial aquifer, but this can vary from location to location throughout Long Island. The upper glacial aquifer, which lies from the surface down to a depth of approximately 220 feet, consists of glacial till, which is unsorted clay, sand, gravel, and lacustrine or marine deposits consisting of clay, silt, and sand. The glacial till may cause localized, perched water conditions and retard downward percolation of precipitation. However, the outwash deposits are highly permeable. In general, this formation contains the water table for Long Island and recharges all underlying aquifers. Beneath the site, the water table is at a depth of approximately 45 to 50 ft MSL. Groundwater is moving south or southeast.

Ref. No. 18

3. Is a designated sole source aguifer within 3 miles of the site?

All aquifers on Long Island are federally designated as sole source aquifers.

Ref. No. 19

4. What is the depth from the lowest point of waste disposal/storage to the highest seasonal level of the saturated zone of the aquifer of concern?

The lowest point of waste disposal was in the cesspool, which has an unknown depth; therefore, the lowest point of waste disposal is assumed to be 6 ft below ground surface. The ground surface is approximately 70 ft MSL, and the water table is approximately 45 to 50 ft MSL. Therefore, the depth from the lowest point of waste disposal to the water table aquifer is approximately 15 to 20 ft.

Ref. Nos. 18, 20

5. What is the permeability value of the least permeable continuous intervening stratum between the ground surface and the aquifer of concern?

The least permeable continuous stratum between the ground surface and the Magothy aquifer has a permeability value estimated to be 10⁻³ cm/sec or greater.

Ref. Nos. 18, 21

| 6. | What is the | net preci | pitation | for the | area? |
|----|-------------|-----------|----------|---------|-------|
|----|-------------|-----------|----------|---------|-------|

The net precipitation in the area of the site is approximately 14 inches.

Ref. No. 21.

7. Identify uses of groundwater within 3 miles of the site (i.e., private drinking source, municipal source, commercial, industrial, irrigation, unusable).

Groundwater is used for municipal water supply in the area of the site.

Ref. No. 22

8. What is the distance to and depth of the nearest well that is currently used for drinking or irrigation purposes?

| Distance Approximately 1 mile. | Depth | Unknown | |
|--------------------------------|-------|---------|--|
| Ref. No. 22 | | | |

9. Identify the population served by the aquifer of concern within a 3-mile radius of the site.

The population served by groundwater within 3 miles of the site is approximately 931,000.

Ref. No. 22

SURFACE WATER ROUTE

10. Describe the likelihood of a release of contaminant(s) to surface water as follows: observed, alleged, potential, or none. Identify the contaminant(s) detected or suspected, and provide a rationale for attributing the contaminants to the facility.

With the available background information it was not possible to determine whether storm water runoff from the site entered infiltration basins or the Carlls River. If storm water runoff enters the Carlls River, there is a potential that a release to surface water occurred during the operation of the cesspool.

Ref. Nos. 20, 23

11. Identify and locate the nearest downslope surface water. If possible, include a description of possible surface drainage patterns from the site.

If the storm water runoff enters the Carlls River, then runoff from the site would follow city streets and/or storm drains at least 1 mile before entering the river.

12. What is the facility slope in percent? (Facility slope is measured from the highest point of deposited hazardous waste to the most downhill point of the waste area or to where contamination is detected.)

The facility slope is estimated to be less than 3 percent.

Ref. No. 1

13. What is the slope of the intervening terrain in percent? (Intervening terrain slope is measured from the most downhill point of the waste area to the probable point of entry to surface water.)

The slope of the intervening terrain is estimated to be less than 1 percent. The elevation change from the site to the Carlls River is approximately 20 ft, and the shortest possible overland route is approximately 4800 ft.

 $\frac{100 \text{ percent x } 20 \text{ ft}}{480 \text{ ft}} = 0.4 \text{ percent}$

Ref. No. 20

14. What is the 1-year 24-hour rainfall?

The 1-year 24-hour rainfall in the area of the site is approximately 2.7 inches.

Ref. No. 21

15. What is the distance to the nearest downslope surface water? Measure the distance along a course that runoff can be expected to follow.

If the storm water runoff enters the Carlls River, then runoff from the site to the Carlls River would travel at least 1 mile.

Ref. No. 20

16. Identify uses of surface waters within 3 miles downstream of the site (i.e., drinking, irrigation, recreation, commercial, industrial, not used).

The Carlls River runs through Belmont Lake State Park where it may be used for recreational purposes.

Ref. No. 20

17. Describe any wetlands, greater than 5 acres in area, within 2 miles downstream of the site. Include whether it is a freshwater or coastal wetland.

The nearest wetlands to the site along the Carlls River are approximately 2.5 miles from the probable point of entry.

Ref. No. 20

18. Describe any critical habitats of federally listed endangered species within 2 miles of the site along the migration path.

There are no federally listed endangered species within 2 miles of the site.

19. What is the distance to the nearest sensitive environment along or contiguous to the migration path (if any exist within 2 miles)?

No sensitive environment is known to exist along the potential migration pathway.

20. Identify the population served or acres of food crops irrigated by surface water intakes within 3 miles downstream of the site and the distance to the intake(s).

No surface water intakes are known to exist along the potential migration route.

Ref. Nos. 20, 22

21. What is the state water quality classification of the water body of concern?

The state water classification of the Carlls River north of the Montauk Highway is "C." Class "C" is suitable for fishing and fish propagation.

Ref. No. 25

22. Describe any apparent biota contamination that is attributable to the site.

No biota contamination was noted in available background information or during the off-site reconnaissance.

Ref. No. 1

AIR ROUTE

23. Describe the likelihood of a release of contaminant(s) to the air as follows: observed, alleged, potential, none. Identify the contaminant(s) detected or suspected, and provide a rationale for attributing the contaminant(s) to the facility.

There is no potential for a release of contaminants to the air because the contaminants are metals that do not volatilize.

Ref. No. 9

24. What is the population within a 4-mile radius of the site?

The population within 4 miles of the site is approximately 170,300.

Ref. No. 26

FIRE AND EXPLOSION

25. Describe the potential for a fire or explosion to occur with respect to the hazardous substance(s) known or suspected to be present on site. Identify the hazardous substance(s) and the method of storage or containment associated with each.

There is no potential for a fire or explosive condition to occur due to the hazardous metals disposed of in the cesspool.

26. What is the population within a 2-mile radius of the hazardous substance(s) at the facility?

The population within 2 miles of the site is approximately 57,900.

Ref. No. 26

DIRECT CONTACT/ON-SITE EXPOSURE

27. Describe the potential for direct contact with hazardous substance(s) stored in any of the waste units on site or deposited in on-site soils. Identify the hazardous substance(s) and the accessibility of the waste unit.

There is a potential for direct contact with soils contaminated by the operation of the cesspool, as there are no fences restricting public access.

Ref. No. 1

28. How many residents live on a property whose boundaries encompass any part of an area contaminated by the site?

There is no area that has been documented as being contaminated.

29. What is the population within a 1-mile radius of the site?

The population within 1 mile of the site is approximately 20,300.

PART IV: SITE SUMMARY AND RECOMMENDATIONS

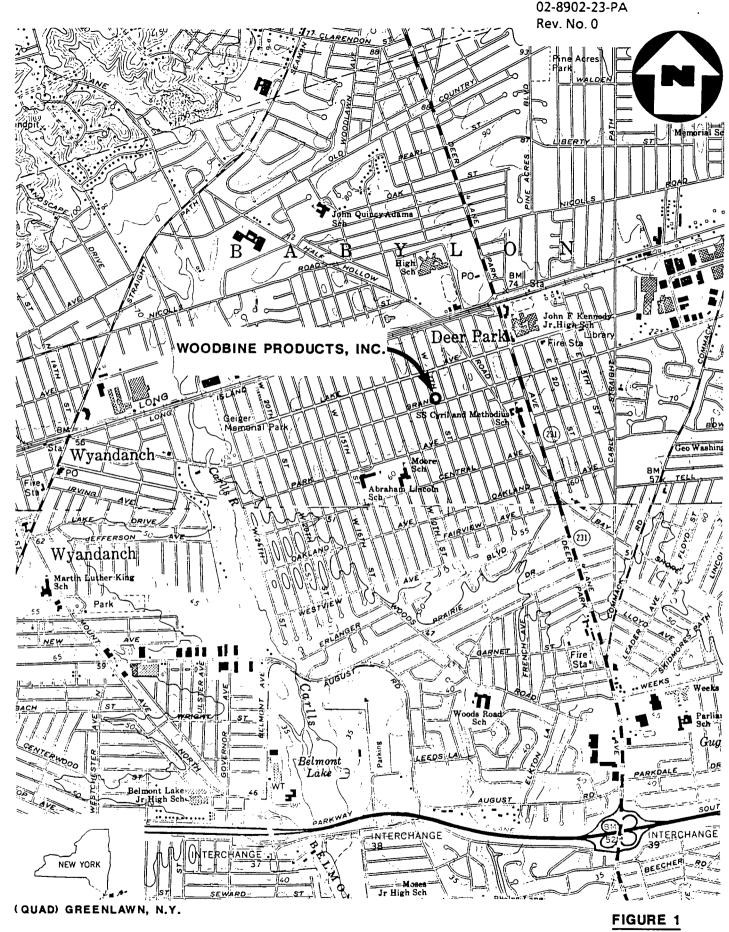

The Woodbine Products, Inc. Site is located in Deer Park, Suffolk County, Long Island, New York. Woodbine Products, Inc. owns approximately 3 acres of property in a heavily populated section of Long Island and produces electrical circuit boards and chassis. A portion of the production includes chrome plating of parts and cooling of parts. Woodbine Products, Inc. has operated this facility continuously from at least 1967 to the present.

Prior to June of 1977 Woodbine Products, Inc. operated a cesspool (leaching lagoon) to dispose of contact cooling water. This contact cooling water was tested several times, and detectable concentrations of hexavalent chromium, zinc, and other metals were found to be present. In 1975 Woodbine Products, Inc. applied for and received a SPDES permit from the Suffolk County Department of Health to discharge water to the groundwater. This permit was renewed in 1980 for an additional 5 years. Since 1977 Woodbine Products, Inc. has had all hazardous wastes removed from the site by a licensed waste hauler. Until 1983 the frequency of this waste removal exceeded 90 days, and therefore, Woodbine Products, Inc. was considered a RCRA temporary storage facility. However, in 1983 Woodbine Products, Inc. increased the frequency of the hazardous waste removal to every 80 days and thus changed its RCRA status to generator.

Groundwater contamination and direct contact are the two areas of most concern, while surface water is of a lesser concern. Groundwater will have received the greatest volume of water from the cesspool. Within 3 miles of this site there are over 900,000 people who receive potable water drawn from public groundwater wells. Direct contact with the area where the cesspool was located is possible because access to this area is not restricted. Therefore, the local population, approximately 20,000 people within 1 mile, may become accidentally exposed to contaminated soils. Storm water runoff in the area may be channeled to infiltration basins or the Carlls River. If storm water runoff enters the Carlls River and carried contaminants from the Woodbine Products, Inc. Site, then there is a potential for the local population to be exposed while sport fishing in the Carlls River. No record of gross contamination, enforcement actions, or cleanup actions concerning Woodbine Products, Inc. was found in available background information.

Due to the potentially large volume of metal-contaminated wastewater discharged to groundwater, the large number of people dependent upon groundwater, and the large number of people who may be accidentally exposed to contaminated surface soils, a **MEDIUM** priority site inspection is recommended. This site inspection should include groundwater samples from the on-site monitoring well and from the monitoring wells on adjacent properties. Surface soil samples should be collected from the area where the cesspool was located to determine whether direct exposure is still a potential. Finally, the destination of storm water runoff, (infiltration basin or the Carlls River) should be determined in order to evaluate the potential for surface water contamination.

STATE POLLUTANT DISCHARGE ELIMINATION SYSTEM (SPDES) DISCHARGE PERMIT

Special Conditions (Part I)

This SPDES permit is issued in compliance with Title 8 of Article 17 of the Environmental Conservation Law of New York State and in compliance with the provisions of the Federal Water Pollution Control Act, as amended by the Federal Water Pollution Control Act Amendments of 1972, P.L. 92-500, October 18, 1972 (33 U.S.C. § 1251 et. seq.) (hereinafter referred to as "the Act").

> Woodbine Products, Inc. Attn: Vincent J. Conforti, V.P.

(Full Name of Permittee)

is authorized by William L. Garvey, P.E., Chief, PDES Permit Section (Designated Representative of Commissioner of the Department of Environmental Conservation)

to discharge from 701 Grand Boulevard

(Street Address of Discharging Facility)

Deer Park, New York 11729

Babylon (T), Suffolk County

to groundwater, Class GA

(Name of Receiving Waters)

in accordance with the following special and general conditions:

The specific effluent limitations and other pollution controls applicable to the discharge permitted herein are set forth in the special conditions. Also set forth are self-monitoring and reporting requirements. Unless otherwise specified, the permittee shall submit original copies of all reports to the Central Office and the appropriate Regional Office of the Department of Environmental Conservation and the EPA Region II Regional Administrator. Except for data determined to be confidential under Section 17-0805 of the Environmental Conservation Law or Section 308 of the Act, all such reports shall be available for public inspection at the offices of the Department of Environmental Conservation and the Regional Administrator of EPA Region II. Knowlingly making any false statement on any such report may result in the imposition of criminal penalties as provided for in Section 71-1933 of the Environmental Conservation Law or Section 300 of the Act.

Final Effluent Limitations

During the period beginning effective date of permit and lasting

(Give Date)

until the date of expiration of this permit, discharges from outfalls 001, 002, and 003

(Specify Outfall Number shall be limited and monitored by the permittee as specified below:

(a) The following shall be limited and monitored by the permittee as specified:

Discharge Limitation Monitoring in kg/day (lbs./day) Other Limitations Requirements Outfall Effluent Daily (Specify Units) Measurement Sample Characteristic Average Maximum Average Maximum Number Frequency INDUSTRIAL WASTE HOLDING TANK - NO DISCHARGE ALLOWED ALL WASTES MUST BE REMOVED BY AN APPROVED LICENSED INDUSTRIAL WASTE SCAVENGER. WASTE REMOVAL RECORDS MUST BE MAINTAINED FOR INSPECTION BY REPRESENTATIVES OF NYSDEC OR SCOEC. WASTE REMONAL SUMMARY MUST BE SUBMITTED TO NYSDEC +SCHEC EVERY 001 Sanitary wastes only - no monitoring required.

PERMITTEE ALSO SUBJECT TO ATTACHED SCHENIE A

For the purposes of this subsection, the daily average discharge is the total discharge by weight during a calendar month divided by the number of days in the month that the production or commercial facility was operating.

For the purposes of this subsection, the daily maximum discharge means the total discharge by weight during any calendar day.

| | (b) | The pH shall r | not be less | than | 6.5 | _ nor g | greater | than | 8.5 | |
|--------|-------|-----------------|-------------|-------|-------|---------|----------|---------|-----|-------|
| The pH | shall | be monitored as | s follows: | daily | usina | proper | rly cali | lbrated | На | meter |

Monitoring Locations

Permittee shall take samples and measurements to meet the monitoring requirements at the location indicated below: (Show locations of outfalls with sketch or flow diagram as appropriate).

c. space for additional process codes or for describing other processes (code "T04"). For each process entered here INCLUDE DESIGN CAPACITY.

IV. DESCRIPTION OF HAZARDOUS WASTES

- EPA HAZARDOUS WASTE NUMBER Enter the four-digit number from 40 CFR, Subpart D for each listed hezardous waste you will handle. If you handle hazardous wastes which are not listed in 40 CFR, Subpart D, enter the four-digit number(s) from 40 CFR; Subpart C that describes the characteristics
- tics and/or the toxic contaminants of those hazardous wastes.

 ESTIMATED ANNUAL QUANTITY For each listed waste entered in column A estimate the quantity of that waste that will be handled on an annual haris. For each characteristic or the property of the contaminants of those hazardous wastes. basis. For each characteristic or toxic contaminant entered in column A estimate the total annual quantity of all the non-listed waste(s) that will be handled which possess that characteristic or contaminant.
- UNIT OF MEASURE For each quantity entered in column B enter the unit of measure code. Units of measure which must be used and the appropriate codes are: the second second second

| ENGLISH UNIT OF MEASURE CODE | METRIC UNIT OF MEASURE CODE |
|------------------------------|-----------------------------|
| POUNDSP | KILOGRAMS |
| TONS | METRIC TONS |

If facility records use any other unit of measure for quantity, the units of measure must be converted into one of the required units of measure taking into account the appropriate density or specific gravity of the waste.

PROCESSES

- 1. PROCESS CODES:
- For listed hazardous waste: For each listed hazardous waste entered in column A select the code(s) from the list of process codes contained in Item [1] to indicate how the waste will be stored, treated, and/or disposed of at the facility.
 - For non-listed hazardous wastes: For each characteristic or toxic contaminant entered in column A, select the code/s/ from the list of process codes contained in Item III to indicate all the processes that will be used to store, treat, and/or dispose of all the non-listed hezerdous wastes that possess that characteristic or toxic contaminant.

Note: Four spaces are provided for entering process codes, if more are needed: (1) Enter the first three as described above; (2) Enter "000" in the extreme right box of Item IV-D(1); and (3) Enter in the space provided on page 4, the line number and the additional code(s).

2. PROCESS DESCRIPTION: If a code is not listed for a process that will be used, describe the process in the space provided on the form.

- OTE: HAZARDOUS WASTES DESCRIBED BY MORE THAN ONE EPA HAZARDOUS WASTE MANUEL MINISTER THAN CON DO CONTIDED BY ore than one EPA Hazardous Waste Number shall be described on the form as follows:
 - 1. Select one of the EPA Hazardous Waste Numbers and enter it in column A. On the same line complete columns 8,C, and D by estimating the total annual
 - quantity of the weste and describing all the processes to be used to treat; store, and/or dispose of the weste.

 2. In column A of the next line enter the other EPA Hazardous Waste Number that can be used to describe the waste. In column D(2) on that line enter "included with above" and make no other entries on that line. "Included with above" and make no other entries on that line.

 3. Repeat step 2 for each other EPA Hazardous Waste Number that can be used to describe the hazardous waste.

IPLE FOR COMPLETING ITEM IV (shown in line numbers X-1, X-2, X-3, and X-4 below) - A facility will treat and dispose of an estimated 900 pounds per year of chrome shavings from leather tenning and finishing operation. In addition, the facility will treat and dispose of three non-listed westes. Two westes are corrosive only and there will be an estimated 200 pounds per year of each waste. The other waste is corrosive and ignitable and there will be an estimated 10 pounds per year of that waste. Treatment will be in an incinerator and disposal will be in a landfill.

Re: Woodbine Products, Inc.

701 Grand Boulevard, Deer Park, New York

E.P.A. Id. No. 002061380

Attention: Dr. Richard Baker

Gentlemen:

RICHARD J. GRAF

JOHN L. WALSH

Please be advised that I represent Woodbine Products, Inc., in connection with its compliance with federal requirements pertinent to financial assurance for closure and post-closure costs required of hazardous waste treatment, storage and disposal facilities.

As Woodbine Products, Inc. does not treat or dispose of hazardous waste, the only involvement that Woodbine has as a TSD facility is in the storage of hazardous waste. Further, Woodbine does not receive waste from off-site and the company's only involvement as a storage facility is in storage of hazardous waste at the site of generation.

Therefore, in reviewing the pertinent rules and regulations found in 40 CFR 260-271, and comments thereto, it occurred to me that, perhaps, Woodbine Products, Inc., as a waste generator and storer, could be legally exempt from providing financial assurance by not storing its hazardous waste at the site of generation longer than ninety days, which practice would also promote better enviornmental protection. In discussing this with my client, I learned that it had received a similar comment from a management consultant. Accordingly, Woodbine Products, Inc., has amended its method of operation so that hazardous wastes will be stored on-site for less than ninety days, and then will be sent to a treatment facility that is allowed, under federal and state regulations, to receive the waste.

Accordingly, and on behalf of Woodbine Products, Inc., I request that it be reclassified so as to indicate that it is an exempted hazardous waste storage facility, as provided in 40 CFR 262.34,

To: E.P.A.

Re: Woodbine Products, Inc.

June 20, 1983

Page Two

235.1 (c) (7) and 270.1 (c) (2) (i). (Please note that my client is aware that 40 CFR 262.34 imposes certain obligations on generators who are storing their hazardous wastes for less than ninety days, e.g., personnel training, compliance with certain sections of 40 CFR 265, etc., and has taken steps to insure that all regulatory obligations under 40 CFR 262.34 will be met. A previous notice from your agency, undated but issued by a Mr. Stoller as notice from your agency, undated but issued by a Mr. Stoller as hould a firm determine that it does not meet the definition of a regulated hazardous waste TSD facility, or that its original permit application was in error, the firm should amend or withdraw its permit application. I am uncertain as to which procedure should be followed in this case, i.e., amendment or withdrawal. Please advise me as to which procedure should be followed, and, if any further forms are required, kindly send me same.

Very truly yours,

Richard J. Graf

Woodbine Products, Inc. 701 Grand Houlevard Deer Park, New York 11729

Re: Change of Status under the Resource Conservation and Recovery Act (RCRA) EPA Identification Number: NYD002061380 Site Location: Deer Park, New York

Dear Sir:

By previous notification, you informed the Environmental Protection Agency (EPA) that you conduct activities at the above referenced site involving hazardous wastes, and as such were subject to the requirements of the Solid Waste Disposal Act, as amended by the Resource Conservation and Recovery Act of 1976 (RCRA), as amended, 42 U.S.C. \$6901, et seq. (the Act).

Your letter of June 27, 1983, in which you request declassification or change of status in the RCRA program, has been reviewed by EPA and found adequate in supplying EPA with sufficient information to change the status of your site. Therefore, your facility is now listed in our records as a generator of hazardous waste, and no longer considered a hazardous waste storer.

Please be advised that the determination of your status has been made solely on the basis of applicable federal regulations. The State of New York also regulates the handling of hazardous waste. Therefore, the New York State Department of Environmental Conservation should be consulted regarding state compliance responsibilities.

If you have any questions on this matter, please contact John Hajduk of my staff at (212) 264-9880.

Sincerely yours,

Richard A. Baker, Chief Permits Administration Branch Office of Policy & Management

Subject: Change of Hazardous Waste Activity EPA ID No.: NYD002061380

Dear Mr. Conforti:

This letter formally acknowledges that Woodbine Products, Inc., located in Deer Park, New York, is a generator of hazardous waste. Hased on your letter of June 27, 1983, we note that your organization no longer stores hazardous waste for longer than 90 days and therefore is not required to obtain a federal hazardous waste management permit.

Please call Mr. Tom Taccone of my staff at (212) 264-9880 should you have any questions on this matter.

Sincerely yours,

Richard A. Baker Chief Permits Administration Branch Office of Policy & Management

NOTIFICATION OF UNSATISFACTORY INDUSTRIAL WASTE SAMPLING

Date May 10, 1974

Woodbine Products, Inc. 701 Grand Blvd. Deer Park, N. Y. 11729

Gentlemen:

On April 29, 1974 samples of your industrial waste were taken. The following parameters were found to be unsatisfactory:

- 1. Iron 1.3 mg/1
- 6.

2.

7.

3.

8.

4.

9.

5.

10.

The acceptable limits on each of these parameters according to New York State Groundwater Standards are as follows:

1. Iron - 0.6 mg/1

6.

2.

7.

3.

8.

4.

9.

5.

10.

Please see that these conditions are corrected as soon as possible. If you have any questions or need any assistance, please do not hesitate to contact this office.

Very truly yours,

Roy Gilbert Enforcement Section

RG./rt

June 27, 1977

Suffolk County Department Environmental Control Jetson Lane Hauppauge, New York

Attention:

Roy Gilbert

Dear Mr. Gilbert:

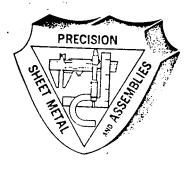

As per our present permit, we have stopped treating our waste water rinse (including caustic, desmuth and alodine) as of May 1977. We have made arrangements with Thomas Patterson Inc. to have our waste water rinse removed from the storage tank located inside our premises on a monthly basis. Our storage tank (about 1200 gallons) has been disconnected from the outside cesspool.

Looking forward for the new permit.

Very truly yours,
WOODBINE PRODUCTS INC.

Re: Containment Plans - SCDHS Job # HM 87-87

Dear Mr. Florio:

I have reviewed your proposed containment plans for compliance with Article 12 of the Suffolk County Sanitary Code. These plans are acceptable.

Enclosed find an approved drawing and a Permit to Construct. This permit expires on September 1, 1987.

Contact this office when construction is completed as an inspection is required. A Permit to Operate a storage facility is required and will be issued upon completed construction approval.

Should you have any questions, please contact me at 451-4649.

Very truly yours,

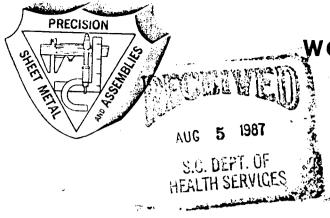

Vincent Frisina, P.E.

Re:

Containment Plans -SCDHS Job #HM87-87

Dear Mr. Frisina:

Pursuant to your letter of April 27, 1987 in reference to the construction of a containment wall, please be advised that the work has now been completed and we will appreciate your inspection of same.

Please contact the undersigned when you specify the date for inspection.

Thank you once again for your cooperation in this matter.

Very truly yours,

Mr. Mauro Florio Woodbine Products, Inc. 701 Grand Boulevard Deer Park, New York 11729

Dear Mr. Florio:

An inspection of your facility on August 25, 1987 by Mr. Bruce Wilson of this office revealed you were in violation of Article 12 Section #760-1206 for constructing a storage area for toxic or hazardous materials in contravention of provisions in the Permit to Construct issued your firm.

Please find enclosed copies of the approved Permit to Construct which called for Preco coating and cement block containment. Any changes concerning the containment area should be submitted to Vincent Frisina, P.E. for approval prior to construction. If you have any questions in this regard, please contact Mr. Frisina directly at 451-4649.

Sincerely,

Robert Seyfarth Senior Sanitarian

Re:

Letter of August 27, 1987

Dear Mr. Frisina:

Pursuant to our telephone conversation with Robert Seyfarth, please be advised of the following changes that were made in the construction of our spill containment.

Per attached revised sketch, a 12" section of the wall was constructed by using an aluminum flashing and 12" of poured concrete in lieu of block to existing block level. The reason for this was to circumvent moving the existing garage door in this 12" area. Also, Thompson Waterproofing, Stock #10105 was used in lieu of Preco Waterproofing.

We hope these changes will meet with your approval and hope to hear from you shortly.

Very truly yours.

SUFFOLK COUNTY WATER AUTHORITY

GEOHYDROLOGY

GEOLOGY AND AQUIFERS

Unconsolidated deposits, ranging in age from Late Cretaceous to Pleistocene, underlie the mid-island area. These deposits contain several major aquifers and constitute the ground-water reservoir. Thin surficial Holocene deposits of soil and some swamp accumulations occur from place to place, but these are of little significance to the ground-water reservoir. The unconsolidated deposits rest unconformably on crystalline bedrock consisting of Precambrian (?) schist and gneiss which is considered to be the bottom of the ground-water reservoir on Long Island.

The unconsolidated deposits, from the bedrock upward, include the Lloyd Sand Member and clay member of the Raritan Formation of Late Cretaceous age, the Matawan Group-Magothy Formation, undifferentiated, also of Late Cretaceous age, and glacial deposits of Pleistocene age. The major aquifers in the area are the deposits of sand and gravel in the Pleistocene and the Matawan-Magothy strata. The test drilling described previously was carried out mostly to the depth of the upper part of the clay member. Therefore, the drilling served to determine the base of the Matawan-Magothy deposits. The drilling also served to obtain information on the configuration of the top of the Matawan-Magothy deposits, which were deeply eroded during Tertiary and, probably, Pleistocene time.

BEDROCK OF THE PRECAMBRIAN (?) SYSTEM

The Precambrian (?) gneiss and schist which underlies Long Island is hard and dense. Virtually all the water in these rocks is found in joints, faults, and foliation planes. Because these openings are usually tight and poorly connected, the bedrock is practically impermeable, especially by comparison with the overlying unconsolidated formations. No wells are known to tap bedrock in the mid-island area.

The bedrock was eroded to a peneplain prior to the deposition of the Cretaceous strata. In the mid-island area, the bedrock surface dips gently southeast at an average slope of about 65 feet per mile (about two-thirds of a degree), and its altitude ranges from about 800 feet below sea level in the northwestern corner of the area to about 1,600 feet below sea level in the southeastern part (pl. 2).

UPPER CRETACEOUS SERIES

Raritan Formation

Lloyd Sand Member

The Lloyd Sand Member of the Raritan Formation comprises the Lloyd aquifer on Long Island. This unit consists mostly of beds and lenses of light- to medium-gray sand and gravelly sand, commonly containing small to large amounts of interstitial clay and silt, that are intercalated with beds and lenses of light- to dark-gray clay, silt, and clayey and silty sand.

Only two drill holes are known to have penetrated the Lloyd in the midisland area. One hole partly penetrated the unit at the Pilgrim State Hospital, in Brentwood. The second hole, which is in the village of Lake Ronkonkoma, and which was one of the test holes drilled as part of this study, fully penetrated the unit. A log of the test hole describing lithology of the Lloyd is shown in table 1, \$33379.

The surface of the Lloyd is roughly parallel to the bedrock surface. The Lloyd surface dips from an altitude of about 550 feet below sea level in the northwestern part of the area, to an altitude of about 1,250 feet below sea level in the southeastern part (pl. 2), and the unit's thickness ranges from about 260 feet to 360 feet from northwest to southeast, respectively. Plate 2 shows contours on the Lloyd surface. Plate 2 also shows contours on the bedrock surface; therefore, the Lloyd's thickness, in any part of the area, can be estimated by computing the local difference between the altitudes of the bedrock and Lloyd surfaces.

The Lloyd aquifer is moderately permeable. Its average horizontal permeability has been estimated by Lusczynski and Swarzenski (1966, p. 19), Isbister (1966, p. 20), and Soren (in press) to range between 400 and 500 gpd per sq ft (gallons per day per square foot) in Queens and Nassau Counties, west of the mid-island area. Warren and others (1968, p. 102) estimated the Lloyd's horizontal permeability to be 165 gpd per sq ft at the Brookhaven National Laboratory, about 12 miles east of the mid-island area. The section of Lloyd penetrated by the test well near Lake Ronkonkoma was fairly sandy and gravelly (table 1, \$33379), and at this site the average horizontal permeability of the Lloyd probably is considerably more than 500 gpd per sq ft. Wells tapping the Lloyd in other parts of Long Island have been pumped at rates of as much as 1,600 gpm (gallons per minute), and the specific capacities of these wells (pumpage, in gallons per minute, divided by drawdown, in feet) have been reported to range from 3 to 40 gpm per foot of drawdown.

At present, there is no pumpage from the Lloyd aquifer in the mid-island area, mainly because of the great depth of the aquifer, and because more permeable aquifers are found at shallower depths. In addition to being at a greater depth, the water from the Lloyd commonly has undesirably high concentrations of iron.

Clay Member

The clay member of the Raritan Formation (commonly referred to as the Raritan clay) completely covers the underlying Lloyd aquifer in the mid-island area, and confines water in that aquifer. The Raritan clay consists mostly of beds and lenses of light- to dark-gray clay, silt, and clayey and silty fine sand (table 1). Thin to thick sandy beds commonly occur in the unit from place to place, but these beds do not have great lateral extent. Laminae and thin beds of lignite and pyrite and disseminated particles of these substances are common in the clay beds of the unit. The thickness of the Raritan clay increases to the southeast, and ranges from about 150 feet in the northwestern part of the mid-island area to about 200 feet in the southeastern part.

The surface of the Raritan clay is roughly parallel to that of the underlying Lloyd Sand Member. The altitude of the surface of the Raritan clay ranges from about 300 feet below sea level in the northwestern part of the mid-island area, to about 1,050 feet below sea level in the southeastern part (pl. 3).

Matawan Group-Magothy Formation, Undifferentiated

The Matawan Group-Magothy Formation, undifferentiated, comprises the Magothy aquifer of Long Island. Deposits in this unit consist of beds and lenses of light-gray fine to coarse sand, containing traces to large amounts of interstitial clay and silt, intercalated with thin to thick beds and lenses of light- to dark-gray clay, silt, and clayey and silty sand (table 1). The clay and silt beds commonly contain laminae and thin beds of lignite. Disseminated lignite and pyrite also are common in the sand beds of the aquifer. Gravelly coarse sand is commonly found in the basal part of the aquifer. This coarse zone ranges in thickness from 100 to 150 feet west of the mid-island area to 150 to 200 feet in the mid-island area. The basal zone also commonly contains abundant interstitial clay and silt and many thin to thick beds and lenses of clay, silt, and clayey and silty sand.

The surface of the Magothy aquifer (pl. 4) is not planar as are the surfaces of the underlying units. The Magothy surface was deeply eroded during Tertiary time, and probably was considerably eroded in Pleistocene time. Consequently, the depth to the Magothy aquifer and the aquifer's thickness cannot be predicted as accurately as the depths and thicknesses of the underlying units. Many control points in addition to those already known are needed to accurately map the upper surface of the Magothy aquifer.

The highly irregular character of the surface of the Magothy aquifer is shown in plate 4. The upper surface of the aquifer ranges in altitude from as high as about 200 feet above sea level to as low as about 500 feet below sea level. The Magothy was completely removed by erosion in a buried valley near the South Huntington area, and in that area upper Pleistocene deposits lie directly on the Raritan clay. This buried valley was called the "Huntington buried valley" by Lubke (1964, pl. 3), and as mapped by Lubke, the valley extended about 2-1/2 miles south of the Northern State Parkway.

Information from wells drilled after Lubke's investigation indicates that the Huntington buried valley continues southeastward, joining another buried valley in the Deer Park area. From Deer Park, the valley appears to extend southeastward across Long Island to the Fire Island Pines area of Fire Island, about 10 miles southeast of Deer Park, where the Magothy surface was shown to be about 350 feet below sea level by Perlmutter and Todd (1965, pl. 8).

The Huntington and Deer Park buried valleys are separated by a divide across the buried valley system in the Deer Park area. The Huntington buried valley slopes steeply northwestward from the divide; the Deer Park buried valley has a gentle southward slope toward the Fire Island Pines area. The divide across the valley approximately coincides with the southern margin of the Ronkonkoma terminal moraine. (See the following section, "Pleistocene Series.") The steeper Huntington buried valley was probably overdeepened by scouring action of Pleistocene glaciation. Other buried valleys in the northern part of the mid-island area (pl. 4) are not as deep nor as extensive as the Huntington and Deer Park buried valleys.

A large depression in the Magothy surface is apparent in the St. James-Ronkonkoma area. Lubke (1964, pl. 3) showed the Magothy surface to be more than 200 feet below sea level in this area. More recent information indicates that the Magothy surface in this area is more than 500 feet below sea level (pl. 4). This large depression is here called the Ronkonkoma basin (pls. 4-5). The precise origin of this basin is not known, but it probably was at least partly a result of Pleistocene glacial scouring of a pre-existing valley system. The depression appears to have had no outlet, and its southernmost end coincides approximately with the southern margin of the Ronkonkoma terminal moraine.

Representative thicknesses of the Magothy aquifer are shown in geologic sections in plate 5. In these sections, the thickness of the Magothy ranges from about 300 to 800 feet. The estimated thickness of the Magothy aquifer in any part of the mid-island area can be computed by determining the difference between altitudes of the Magothy and Raritan surfaces as shown in plates 3 and 4. The Magothy aquifer is thickest (about 950 feet) in the southeastern corner of the project area, and it is thinnest in the bottom of the buried valleys. As previously noted, the aquifer is completely missing in part of the buried valley near South Huntington (pl. 4).

The permeability of the Magothy aquifer ranges widely. The estimated average horizontal permeability of the aquifer is about 500 gpd per sq ft in Nassau and Queens Counties (Lusczynski and Swarzenski, 1966, p. 19; Isbister, 1966, p. 23-24; and Soren, in press); however, the permeabilities of some beds in the aquifer may be as high as 2,000 gpd per sq ft (Isbister, 1966, p. 23). Public-supply wells screened in the Magothy aquifer of the mid-island area have yielded as much as 1,700 gpm, with specific capacities ranging from about 14 to 85 gpm per ft of drawdown.

PLEISTOCENE SERIES

Upper Pleistocene deposits

Pleistocene deposits of glacial origin mantle the surface of the midisland area (pl. 1) and range in thickness from a few tens of feet in some localities to more than 600 feet in buried valleys. The approximate thickness of Pleistocene deposits at any place generally can be computed by determining the difference between the altitude of the land surface and the altitude of the surface of the Magothy aquifer.

Most and perhaps all the glacial materials on Long Island were deposited in Wisconsin time, and these materials generally are collectively termed upper Pleistocene deposits. The upper Pleistocene deposits in the mid-island area include terminal moraines, outwash deposits, ground moraine, and lake deposits. The Harbor Hill and Ronkonkoma terminal moraines form the irregular ridges trending east-northeast across the area. Outwash deposits derived from melted glacial ice lie south of the Ronkonkoma terminal moraine. Glacial lake deposits, which apparently were formed between the Ronkonkoma and Harbor Hill advances of the glaciers, lie within outwash deposits below the land surface, and occur mostly between the terminal moraines in the eastern half of the area, most notably in the Smithtown-St. James-Ronkonkoma area.

Ronkonkoma Terminal Moraine

The Ronkonkoma terminal moraine marks the farthest advance of glaciation on Long Island. The moraine is composed largely of crudely stratified sand and gravel. It underlies the highest parts of the mid-island area, tapering from an irregular broad band in the western part, to an irregular narrow ridge in the eastern part. (See plate 1.) The unit lies mostly above the water table and is, therefore, practically of no significance as a source of ground water; however, it is a difficult unit to drill through because of the large amounts of gravel, cobbles, and scattered boulders that it contains.

Harbor Hill Terminal Moraine

Only a very small part of this moraine is found in the mid-island area, in the extreme northwest corner near South Huntington (pl. 1). Most of this moraine is north of the mid-island area. The moraine's lithology and water-bearing characteristics are similar to those of the Ronkonkoma terminal moraine.

Outwash Deposits

The outwash deposits, which are found south of the Ronkonkoma terminal moraine and between the Harbor Hill and Ronkonkoma terminal moraines (fig. 2), are beds of sand and gravel that were deposited by glacial melt water. The

source of the rock materials in the outwash deposits is manifold. As the glaciers moved southward to Long Island, they plucked the bedrock and soils of the surfaces they slid over. Rock materials were incorporated into the ice in contact zones and were also pushed along the glacial front. As the ice melted in late Pleistocene time, the various rock materials were carried away by broad coalescing streams and sheets of water. Consequently, the outwash deposits are stratified, and because of the varied materials carried by the glacier, these deposits consist of a heterogeneous suite of rock types. The great diversity of rock and mineral suites in the Pleistocene deposits, along with the chemically unstable (easily decomposed) rocks and minerals, commonly facilitates differentiation of glacial from the Cretaceous deposits on Long Island.

Outwash deposits underlie the plain in the mid-island area south of the Ronkonkoma terminal moraine, where the major source of glacial deposition was material from the Ronkonkoma ice advance. A readvance of the glacial front followed recession of the Ronkonkoma ice front and resulted in the formation of the Harbor Hill terminal moraine. Lakes were formed in depressions and valleys between the Ronkonkoma and Harbor Hill terminal moraines, and clayey materials were deposited in these lakes. The intermorainal areas also contain recessional deposits of outwash and ground moraine (see the following section, "Ground-Moraine Deposits") from the Ronkonkoma and Harbor Hill deglaciations, and these materials buried the clayey lake deposits.

The outwash deposits are thickest in the buried valleys and thinnest where the Cretaceous surface is closest to land surface (pl. 5). These deposits generally extend below the water table, and are a major source of ground water. Outwash deposits comprise most of the so-called upper glacial aquifer of Long Island, and because these deposits of sand and gravel contain virtually no interstitial clay and silt, the upper glacial aquifer is the most permeable aquifer on Long Island. The estimated average horizontal permeability of the outwash deposits is about 1,000 to 1,500 gpd per sq ft (Lusczynski and Swarzenski, 1966, p. 17; and Soren, in press). Warren and others (1968, p. 75) computed the horizontal permeability of outwash to be about 1,300 gpd per sq ft at the Brookhaven National Laboratory, east of the mid-island area. A horizontal permeability for outwash as high as about 2,500 gpd per sq ft has been reported in Nassau County, west of the project area (Isbister, 1966, p. 29).

Public-supply and other high-capacity wells screened in glacial outwash on Long Island have yielded as much as 1,700 gpm, and reported specific capacities of such wells range from less than 10 gpm per foot of drawdown to as much as about 200 gpm per foot of drawdown; however, the specific capacities range mostly from 50 to 100 gpm per foot of drawdown. (See section "Yields of Individual Wells.")

Ground-Moraine Deposits

Ground-moraine deposits commonly consist of unstratified and unsorted clay, silt, sand, gravel, cobbles, and boulders, deposited on the land surface as the glacial fronts receded. Ground-moraine deposits from the Ronkonkoma advance probably occur beneath the outwash in the area between the Ronkonkoma and Harbor Hill terminal moraines. Some ground-moraine deposits probably were partly reworked by glacial melt water from the Harbor Hill advance and probably appear similar to outwash in drilling samples.

Lake Deposits

A large lake apparently existed between the Ronkonkoma and Harbor Hill terminal moraines in the previously described Ronkonkoma basin. Deposits of light- to dark-brown and gray clay and silt of lacustrine origin, with some included beds of sand and gravel, occur between deposits of outwash in this area. The deposits are informally known as the Smithtown clay unit or Smithtown clay, and they were mapped and described by Lubke (1964, p. 22 and 26) as the "clay unit of Smithtown." Thin to significant thicknesses of this unit were penetrated at four of the test-drilling sites in the eastern half of the mid-island area. (See plate 5 and table 1, S22577, S22910T, S24769, and S24772). Apparently, it is thickest near the community of Lake Grove (not shown in plate 1) about 2.5 miles north of Lake Ronkonkoma, where about 300 feet of Pleistocene clay beds were penetrated in a drilled test hole (Jensen, H. M., oral commun., 1969).

Smaller glacial lakes probably also existed in other parts of the intermorainal area. Many drilling logs from localities in the area indicate thin intercalated clay and fine sand beds between sand and gravel deposits. The extent of these lakes is not fully known, and they were probably small compared to the lake in which the Smithtown clay was deposited.

Veatch and others (1906, p. 61) suggested that present Lake Ronkonkoma, in the eastern part of the mid-island area, is in a depression made by a large ice block that was detached from the main glacial-front mass and buried by outwash deposits. Subsequent melting of the ice block presumably caused the depression in the land surface which then filled with water. Inasmuch as this study has shown that present Lake Ronkonkoma is in the Ronkonkoma basin, it seems possible that the location of the lake may merely reflect the fact that the ancient Ronkonkoma basin was not completely filled by glacial deposits.

The lake deposits do not yield significant quantities of water to wells because they are fine-textured and, accordingly, poorly permeable. However, the lake beds are hydrologically significant because they confine water in the underlying outwash deposits.

Miscellaneous Deposits

The Mannetto Gravel, of Pliocene age, and the Gardiners Clay, a Pleistocene interglacial marine deposit of pre-Wisconsin age, are two additional units of hydrologic signifiance in some parts of Long Island. However, their location and extent in the project area are poorly known, and they seem to occur in only a small part of the area.

The Mannetto Gravel was described and mapped by Fuller (1914, p. 80-85) from the western edge of the mid-island area to about as far east as the area between Wyandanch and Deer Park. The unit reportedly crops out at the tops of high hills, or near the crests of high hills capped by Ronkonkoma terminal moraine deposits. The author could not verify the location and extent of the Mannetto; consequently, the unit is not shown on the surficial geology map (pl. 1).

The Gardiners Clay is an interglacial marine deposit of Sangamon age. It is generally found in the south shore areas of Long Island where the depth to its surface is commonly 40 or more feet below sea level. The Gardiners Clay overlies Matawan-Magothy strata south of the mid-island area (Perlmutter and Todd, 1965, pl. 8), and some clay beds reported by well drillers in the southern part of the buried valley near Deer Park may be Gardiners Clay. However, this is uncertain, and the unit may not be present in the project area.

GROUND - WATER SYSTEM

SOURCE AND MOVEMENT OF GROUND WATER

The ground water on Long Island has its origin in precipitation that falls on the island. According to Cohen and others (1968, p. 36, 40, and 44), the precipitation on Long Island is disposed of as follows: nearly half returns to the atmosphere by evapotranspiration; a very small amount enters streams by direct runoff; and the remaining half percolates downward through the unconsolidated deposits to the water table and enters the ground-water reservoir.

The general ground-water movement on Long Island is from recharge areas near the center of the island to discharge areas at and near the shorelines. Ground water discharges by seepage into streams and by direct subsurface outflow into salty ground water, which in turn is hydraulically connected with bodies of salty surface water.

The horizontal components of the directions of ground-water flow in the upper glacial aquifer are shown in plate 6. In the vicinity of the major ground-water divide in the mid-island area (pl. 6), ground water generally moves downward from the upper glacial aquifer into the Magothy aquifer, and thence through the Raritan clay into the Lloyd aquifer. The vertical components of downward flow decrease with increasing distance both northward and southward of the divide. Beyond the northern and southern margins of the mid-island area, ground-water flow becomes virtually horizontal. Near

the shorelines, the direction of flow is reversed, and ground-water movement is upward from the deeper aquifers toward the surface. Thus, because of the character of the flow system, under natural conditions virtually all the recharge to the Magothy and Lloyd aquifers in western Suffolk County originated in the mid-island area, and all of that recharge ultimately discharged from the ground-water system near the shorelines.

The movement of ground water through Long Island's aquifers in the horizontal direction is generally more rapid than movement in the vertical direction because of the occurrence of interbedded fine- and coarse-grained layers, and because the largest dimensions of unevenly shaped particles in the individual layers tend to be oriented horizontally. Approximate rates of ground-water movement can be computed from hydraulic gradients and estimated coefficients of permeability and porosities of the aquifers. In 1968, water in the upper glacial aquifers in the project area was moving horizontally at rates from less than 0.5 foot per day at points distant from centers of pumping, to hundreds of feet per day near the screens of pumping wells. At the same time, water in the Magothy aquifer was moving horizontally at rates from less than 0.2 foot per day at points distant from pumping, to hundreds of feet per day near the screens of pumping wells.

HYDRAULIC INTERCONNECTION OF AQUIFERS

The aquifers of Long Island are hydraulically interconnected. Layers of clay and silt within an aquifer or between aquifers serve to confine water below them, but they do not completely prevent the vertical movement of water through them. Ground water moves downward readily through coarse outwash deposits in the upper glacial aquifer. Vertical movement of water through the Magothy aquifer is impeded by beds and lenses of clay and silt. Because the clay and silt strata in the Magothy are not continuous, some water may move around lenses of this material in addition to moving slowly through the fine-grained strata.

The contact between the upper glacial and Magothy aquifers is not regular either in attitude or in composition of the contact surfaces. Glacial deposits in buried valleys are in lateral contact with truncated sandy beds in the Magothy. In the buried valleys water can laterally enter the Magothy at great depth directly from the glacial deposits, rather than the water having to move vertically to the same depth through less permeable Magothy beds. In the Huntington buried valley, glacial deposits extend completely through the Magothy aquifer to the underlying Raritan clay. (See plate 4.) In addition to the good hydraulic continuity between the upper glacial and Magothy aquifers in the buried valleys, good hydraulic continuity occurs between the aquifers outside the buried valleys where glacial sand and gravel deposits lie directly on Magothy sand beds. Thus, a fairly good hydraulic connection exists between the upper glacial and Magothy aquifers over large parts of the mid-island area, and the configuration of the piezometric surface of the Magothy aquifer is generally similar to that of the water table. However, in the mid-island area hydraulic heads in the Magothy are lower than those in the upper glacial aquifer because of the downward component of ground-water movement in the area.

The thick areally persistent Raritan clay that lies between the Magothy and Lloyd aquifers impedes but does not prevent downward movement of ground water into the Lloyd aquifer, and water in the Lloyd is tightly confined between the Raritan clay and bedrock. Downward leakage into the bedrock is negligible.

Figures 2 and 3 show hydrographs of wells screened in the upper glacial aquifer and the Magothy aquifer at the test-drilling sites in Brentwood and Hauppauge. At both sites, the heads in the deepest wells in the Magothy aquifer are about 2.5 to 3 feet lower than the heads in the shallowest wells in the upper glacial aquifer. The loss of head downward reflects the downward movement of ground water in the mid-island area. The hydrographs in figures 2 and 3 show that the heads in these two aquifers in the project area decrease at a fairly uniform rate with increasing depth. In addition, water-level fluctuations in the two groups of wells were very similar. Both of these facts, the uniform decrease in head and the similar water-level fluctuations, reflect the high degree of hydraulic interconnection between the upper glacial and Magothy aquifers.

The average vertical permeability of the Magothy aquifer is only poorly known. Estimates range from less than 1 to about 30 gpd per sq ft. Assuming that it averages about 5 gpd per sq ft in the mid-island area, the computed amount of downward ground-water movement through the Magothy aquifer in the vicinity of the ground-water divide in 1968 was about 0.4 mgd (million gallons per day) per square mile, and the estimated velocity of the downward movement was about 0.006 foot per day.

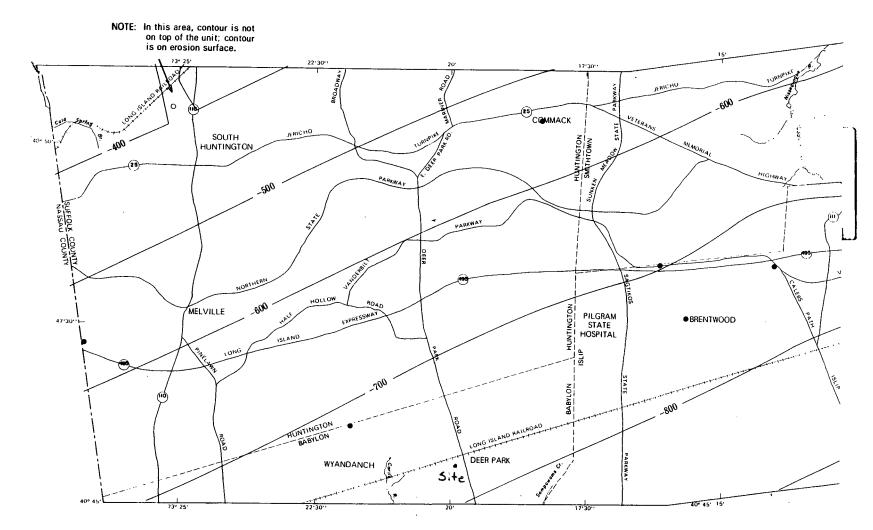

Because of the low permeability of the Raritan clay, the hydraulichead loss across this unit is very much larger than the head loss ecross a comparable thickness of the Magothy and upper glacial aquifers. At the easternmost test site in the village of Lake Ronkonkoma, wells were screened near the base of the Magothy and near the top of the Lloyd aquifers (pl. 5, section A-A', \$33379-80). In 1968, the head near the base of the Magothy aquifer (about 45.5 feet above sea level) was about 11.5 feet higher than the head in the Lloyd aquifer (about 34 feet above sea level). Head losses across the Raritan clay at localities east and west of the Lake Ronkonkoma area differ considerably. At Upton, about 12 miles east of the mid-island area, the head loss across the clay was about 6 feet in 1968; and at Plainview (in Nassau County), about 3 miles southwest of Melville, the head loss across the clay was about 42 feet. The differences in head loss from place to place are largely a result of differences in the vertical permeability and thickness of the Raritan clay.

The head in the Lloyd aquifer at Lake Ronkonkoma in 1968 (about 34 feet above sea level) was higher than either of the heads in the Lloyd at Upton (about 30.5 feet above sea level) and at the Suffolk-Nassau boundary (about 27.5 feet above sea level). The head in the Lloyd at Terryville, about 7 miles northeast of the Ronkonkoma area was about 21 feet above sea level in 1968, and it was 19 feet above sea level at Fire Island State Park in 1968, about 13 miles to the southwest. These data suggest that water in the Lloyd aquifer is moving radially from the Lake Ronkonkoma area. The estimated rate of horizontal movement of water in the Lloyd aquifer in the project area in 1968, was on the order of 0.1 foot per day.

AQUIFERS UNDERLYING NASSAU AND SUFFOLK COUNTIES, NEW YORK

Determination

Notice is hereby given that pursuant to Section 1424(e) of the Safe Drinking Water Act (42 U.S.C. 300f, 360h-3(e); 88 Stat. 1660 et seq.; Pub. L. 93-523) the Administrator of the Environmental Protection Agency has determined that the aquifer system underlying Nassau and Suffolk Counties, Long Island, New York, is the principal source of drinking water for these counties and that, if the aquifer system were contaminated, it would create a significant hazard to public health.

BACKGROUND

The Safe Drinking Water Act was enacted on December 16, 1974, Section 1424(e) of the Act states: "If the Administrator determines, on his own initiative or upon petition, that an area has an aquifer which is the sole of principal drinking water source for the area and which, if contaminated, would create a significant hazard to public health, he shall publish notice of that determination in the FEDERAL REGISTER. After the publication of any such notice, no commitment for Federal financial assistance (through a grant, contract, loan guarantee, or otherwise) may be entered into for any project which the Administrator determines may contaminate such

aquifer through a recharge zone so as to create a significant hazard to public health but a commitment for Federal financial assistance may, if authorized under another provision of law, be entered into to pian or design the project to assure that it will not so contaminate the aquifer."

On January 21, 1975, the Environmental Defense Fund petitioned the designate Administrator to the aquifers underlying Nassau and Suffolk Counties, Long Island, New York, as a sole source aquifer under the provisions of the Act. A notice of receipt of this petition, together with a request for comments, was published in the FEDERAL REGISTER. Thursday, June 12, 1975. Written comments were submitted by the Environmental Defense Fund (EDF) on August 7, 1975, supporting their petition. A letter from the Director of the Nassau-Suffolk Regional Planning Board, dated October 1. 1976, requested that designation be delayed until after the completion of the areawide waste management (208) planning process for Long Island.

Because of the limited response to the FEDERAL REGISTER notice, EPA issued a press release and mailed an information sheet to elected officials and environmental groups on Long Island in March 1977. In addition, a presentation was made to the Citizens Advisory Committee (CAC) of the 208 planning agency and to the executive committee of the Long Island Water Conference. In response to these activities EPA received three comments: a letter from EDF questioning why project review would exclude direct Federal projects, a letter from a member of the East Hampton Planning Board expressing support for the designation, and a letter from the CAC requesting that designation be delayed until after the completion and approval of the Long Island 208 plan.

In considering the comments received, we could not agree with the letters requesting further delay since we do not believe that the review process under Section 1424(e) will constrain the options of 208 planning.

On the basis of the information which is available to this Agency, the Administrator has made the following findings, which are the basis for the determination noted above:

(1) The aquifers underlying Nassau and Suffolk Counties are the sole or principal drinking water source for the area. They supply good quality water for about 2.5 million people. Current water supply treatment practice for public supplies is generally limited to disinfection for drinking purposes, with some plants capable of nitrate removal. There are also numerous private sources. There is no alternative source of drinking water supply which could economically replace this aquifer system.

(2) The aquifer system is vulnerable to contamination through its recharge zone. Since contamination of a ground-water aquifer can be difficult or impossible to reverse, contamination of the the aquifer system underlying Nassau and Suffolk Counties. New York, would pose a significant hazard to those people dependent on the aquifer system for drinking purposes.

Among the determinations which the Administrator must make in connection with the designation of an area under Section 1424(e) is that the area's sole or principal source aquifer or aquifers, "if contaminated, would create a significant hazard to public health . . . " Obviously, threats to the quality of the drinking water supply for such a large population could create a significant hazard to public health. The EPA does not construe this provision to require a determination that projects planned or likely to be constructed will in fact create such a hazard; it is sufficient to demonstrate that approximately 2.5 million people depend on the aquifer system underlying Nassau and Suffolk Counties as their principal source of drinking water, and that the aquifer system is vulnerable to contamination through its recharge zone.

Section 1424(e) of the Act requires that a Federal agency may not commit funds to a project which may contaminate the aquifer system through a recharge zone so as to create a significant hazard to public health. The recharge zone is that area through which water enters into the aquifer system. Because of groundwater movement within these aquifers, the recharge zone is considered to be the entire area of Nassau and Suffolk Counties. However, both horizontal and vertical boundaries of the recharge zone are discussed in the background document under the section entitled "Area of Consideration."

The data upon which these findings are based are available to the public and may be inspected during normal business hours at the office of the Environmental Protection Agency, Region II. 26 Federal Plaza, New York, New York 10007. It includes a support document for designation of the aquifers underlying Nassau and Suffolk Counties, New York, and maps of the area within which projects will be subject to review.

A copy of the above documentation is also available at the U.S. Waterside Mall. Environmental Protection Agency. Public Information and Reference Unit. Room 2922, 401 M Street S.W., Washington, D.C. 20460.

The EPA has issued proposed regulations for the selective review of Federal financially assisted projects which may contaminate the aquifer system underlying Nassau and Suffolk Counties, New York, through the recharge

zone so as to create a significant hazard to public health. These proposed regulations were published in the FEDERAL REGISTER issue of September 29, 1977, and public comments were requested. They will be used as interim guidance for project review until their promulgation during 1978.

EPA, Region II, is working with the Federal agencies which may in the near future fund projects in the area of concern to EPA to develop interagency procedures whereby EPA will be notified of proposed commitments for projects which could contaminate the bicounty area's sole source aquifer system. Although the project review process cannot be delegated, the Regional Administrator in Region II will rely to the maximum extent possible upon any existing or future State and local control mechanisms in protecting the ground-water quality of the aquifer system underlying Nassau and Suffolk Counties, New York, Included in the review of any Federal financially assisted project will be coordination with the State and local agencies, Their determinations will be given full consideration and the Federal review process will function so as to complement and support State and local mechanisms.

Dated: June 12, 1978.

Douglas M. Costle, Administrator.

LOCATION OF COMMUNITY WATER SYSTEM SOURCES-1982

Catalog of Recharge Basins on Long Island, New York, in 1969

by
G. E. Seaburn and D. A. Aronson
U.S. Geological Survey

BULLETIN 70 1973

RECHARGE BASINS

Most of the recharge basins on Long Island are unlined open pits that dispose of storm runoff from residential, commercial, and industrial areas, and from highways (Seaburn, 1970). About 30 basins solely dispose of effluent from sewage-treatment plants. Those basins were not included in the study and are not considered in this report. The area of basins that dispose of storm runoff generally ranges from 0.1 to 30 acres and averages 1.5 acres. The average depth below land surface is 10 feet, but the depth of a few is as much as 40 feet. Storm runoff to recharge basins flows by gutters to street inlets. The street inlets are interconnected by sewers that carry storm water into the basins, where it infiltrates moderately to highly permeable sand and gravel deposits above the ground-water reservoir. Figure 2 shows the location of all the inventoried recharge basins that received storm runoff on Long Island in 1969.

Design and construction of recharge basins on Long Island is regulated and approved by the local governments. Available information on completed basins varies greatly in detail. None of the departments of local government maintains an up-to-date catalog of the type of data presented here.

SOURCES OF DATA

Data were compiled from several sources. These included engineering drawings of proposed land developments; maps of topography, water-table contours, geology, and soils; and aerial photographs.

Most of the data were obtained from engineering drawings of land developments filed with the local government's department responsible for regulating and approving construction designs. In general, the drawings contain the following information: A basin's location, date of construction, design capacity, actual capacity, dimensions, use, bottom altitude, overflow altitude, and land-surface altitude.

U.S. Geological Survey topographic maps were used to verify basin locations and land-surface altitudes of many basins. Aerial photographs were also used to verify basin locations.

The recharge basins were plotted on base maps from which the nearest street intersection as well as the latitude and longitude of each basin were determined.

A water-table contour map developed by Kimmel (1971) was used to estimate water-table altitudes below each basin. Geologic maps (Fuller, 1914; Perlmutter and Geraghty, 1963; Swarzenski, 1963; Lubke, 1964; Isbister, 1966; and Soren, 1970) and soil maps (Lounsbury and others, 1928; and Warner, 1969) were used to determine geologic and soil environment at each basin.

Ms. Diane Trube NUS Corp. 1090 King Georges Post Road Suite 1103 Edison, New Jersey 08837

Re: Farmingdale - Lindenhurst Sites

Dear Ms. Trube:

I have reviewed your request of 11/22/88, and have the following responses to your questions:

- 1. No "critical habitats" for federally listed endangered species have been designated for Long Island as of this date.
- 2. Please contact Mr. Philip Barbato, of our Water Unit, at 516-751-7900, ext. 226.
- 3. Please contact Mr. Charles Guthrie of our Freshwater Fisheries Unit at 516-751-7900, ext 263.

If I can be of further assistance, please do not hesitate to contact me at 751-7900, ext. 248.

Sincerely,

Michael S. Scheibel

Senior Wildlife Biologist

CLASS "B"

Best usage of waters. Primary contact recreation and any other uses except as a source of water supply for drinking, culinary or food processing purposes.

Quality Standards for Class "B" Waters

Items

Specifications

1. Coliform.

The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations, and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.

2. pH

Shall be between 6.5 and 8.5.

3. Total dissolved solids.

None at concentrations which will be detrimental to the growth and propagation of aquatic life. Waters having present levels less than 500 milligrams per liter shall be kept below this limit.

4. Dissolved oxygen.

For cold waters suitable for trout spawning, the DO concentration shall not be less than 7.0 mg/l from other than natural conditions. For trout waters, the minimum daily average shall not be less than 6.0 mg/l. At no time shall the DO concentration be less than 5.0 mg/l. For non-trout waters, the minimum daily average shall not be less than 5.0 mg/l. At no time shall the DO concentration be less than 4.0 mg/l.

CLASS "C"

Best usage of waters. The waters are suitable for fishing and fish propagation. The water quality shall be suitable for primary and secondary contact recreation even though other factors may limit the use for that purpose.

Quality Standards for Class "C" Waters

Items

Specifications

1. Coliform.

The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations, and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.

Shall be between 6.5 and 8.5.

Total dissolved solids.

None at concentrations which will be detrimental to the growth and propagation of aquatic life. Waters having present levels less than 500 milligrams per liter shall be kept below this limit.

4. Dissolved oxygen.

For cold waters suitable for trout spawning, the DO concentration shall not be less than 7.0 mg/l from other than natural conditions. For trout waters, the minimum daily average shall not be less than 6.0 mg/l. At no time shall the DO concentration be less than 5.0 mg/l. For non-trout waters, the minimum daily average shall not be less than 5.0 mg/l. At no time shall the DO concentration be less than 4.0 mg/l.

CLASS "D"

Best usage of waters. The waters are suitable for fishing. The water quality shall be suitable for primary and secondary contact recreation even though other factors may limit the use for that purpose. Due to such natural conditions as intermittency of flow, water conditions not conducive to propagation of game fishery or stream bed conditions, the waters will not support fish propagation.

Conditions related to best usage of waters. The waters must be suitable for fish survival.

Quality Standards for Class "D" Waters

Items

Specifications

1. pH

Shall be between 6.0 and 9.5.

2. Dissolved oxygen.

Shall not be less than 3 milligrams per liter at any time.

3. Coliform.

The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.

Historical Note

Sec. added by renum. and amd. 701.4, filed July 3, 1985; amd. filed Sept. 20, 1985 eff. 30 days after filing.

701.20 Classes and standards for saline surface waters. The following items and specifications shall be the standards applicable to all New York saline surface waters which are assigned the classification of SA, SB, SC or SD, in addition to the specific standards which are found in this section under the heading of each such classification.
